User Profile Backup — Executive Summary

https://isaac-cooper-professional-portfolio.netlify.app/pages/scripting-user-backup

Overview:

An enterprise-ready PowerShell automation that discovers all non-system Windows user profiles, detects associated OneDrive for Business repositories, and captures all data into a single, hostname-labeled ZIP. The workflow eliminates manual backup variability and ensures consistent, auditable data collection for migrations, offboarding, and incident response.

Objectives:

Export complete user profile data, including OneDrive for Business; avoid MAX_PATH issues via short-path staging; generate profile-level and master audit logs; ensure repeatable, operator-friendly execution with structured exit codes.

Architecture:

Scan Profiles → Detect OneDrive Business → Robocopy Staging (short-path) → ZIP Compression → Log & Cleanup

Implementation Highlights:

Discovers all non-system user profiles; identifies OneDrive Business directories; stages data using high-performance Robocopy parameters (/XJ, /ZB, /MT:16); compresses staged data into a device-named ZIP; produces per-profile and master logs for full traceability.

Business Impact:

Reduces migration preparation time; ensures accurate backup of all local + cloud-synced user data; provides consistent and auditable workflow; decreases support overhead and improves operational efficiency.
